Thank you Ms. Kathryn for your prompt reply and valuable information. In an attempt to better understand the configuration of the completion interval in the WDW-410 well, I had reviewed information in the segments of the application document that you referred to, taken this information to the stratigraphic column that I shared with you in late February, and to the log that you provided as well. Each time I observed that there are about twelve shale beds among the sandstones found within the depth interval 6045-6390 feet, and anticipated that the perforations in this well would not appear as a single, continuous interval.

My question of yesterday was prompted by the difficulty for assessing in which layers the additional perforations will be, based on this general description of the proposed completion interval in the Lower Cockfield, and after taking into consideration the fact that, in the original perforated interval, some perforations were placed within the depth interval 6342-6372 feet, which is part of a shale bed.

From your reply, I take it that at this time there is no additional information that would allow preparing an accurate well schematic showing where all the perforations will be. I assume that this information may become available once the well has been re-perforated, and after the operator has submitted a re-completion report to TCEQ. I would appreciate hearing from you in this regard, should this report become available. Thank you again for your efforts and cooperation. Have a nice afternoon.
